

C Programming Basic – week 2

Dynamic allocation, structures

Instructor: Thanh-Chung Dao (chungdt@soict.hust.edu.vn)
Slides by Cao Tuan Dung

1

Topics

- Structures, dynamic allocation review
- Memory Image based File operations
- Exercises

Dynamic Allocation

- Array variables have fixed size, used to store a fixed and known amount of variables – known at the time of compilation
- This size can't be changed after compilation
- However, we don't always know in advance how much space we would need for an array or a variable
- We would like to be able to dynamically allocate memory

3

The malloc function

void * malloc(unsigned int nbytes);

- The function malloc is used to dynamically allocate nBytes in memory
- malloc returns a pointer to the allocated area on success, NULL on failure
- You should always check whether memory was successfully allocated
- Remember to #include <stdlib.h>

```
Example -dynamic_reverse_array
int main(void)
{
   int i, n, *p;

   printf("How many numbers do you want to enter?\n");
   scanf("%d", &n);

/* Allocate an int array of the proper size */
   p = (int *)malloc(n * sizeof(int));
   if (p == NULL)
   {
      printf("Memory allocation failed!\n");
      return 1;
   }
   /* Get the numbers from the user */
   ...
   /* Display them in reverse */
   ...
   /* Free the allocated space */
   free(p);
   return 0;
}
```

Why casting?

The casting in

```
p = (int *)malloc(n*sizeof(int));
is needed because malloc returns void * :
void * malloc(unsigned int nbytes);
```

The type (**void** *) specifies a general pointer, which can be cast to any pointer type.

7

Free the allocated memory

void free(void *ptr);

- We use **free** (**p**) to free the allocated memory pointed to by **p**
- If p doesn't point to an area allocated by malloc, a run-time error occurs
- Always remember to free the allocated memory once you don't need it anymore

Exercise 2.1

- Implement the function my strcat:
 - Input two strings, s1 and s2
 - Output a pointer to a dynamically allocated concatenation
 - For example: The concatenation of "hello_" and "world!" is the string "hello world!"
- Test your function
- Hint: strcpy(s1, s2): copying s2 to s1

9

Structures - User Defined Types

- A collection of variables under a single name.
- A convenient way of grouping several pieces of related information together.
- Variables in a **struct** (short for structure) are called members or fields.

```
Defining a struct

struct struct-name

{

field-type1 field-name1;
 field-type2 field-name2;
 field-type3 field-name3;
...
};
```

Example – complex numbers

```
struct complex {
    int real;
    int img;
};
struct complex num1, num2,
    num3;
```

Typedef

We can combine the typdef with the structure definition:

```
typedef struct complex {
    int real;
    int img;
 } complex t;
complex t num1, num2;
```

13

Exercise 2.2

```
    Given two following structure:

typedef struct point
     double x;
   double y;
} point t;
typedef struct circle
     point_t center;
     double radius;
} circle t;
  Write a function is in circle which returns 1 if a point p is covered by circle c. Test this function
  by a program.
```

Working mode for binary file

	mode	Description	
1	"rb"	opens an existing binary file for reading.	
7	"wb"	creates a binary file for writing.	
	"ab"	opens an existing binary file for appending.	
	"r+b"	opens an existing binary file for reading or writing.	
ı	"w+b"	creates a binary file for reading or writing.	
	"a+b"	opens or create an existing binary file for appending.	

16

File handle: Working with a bloc of data

- Two I/O functions: fread() and fwrite(), that can be used to perform block I/O operations.
- As other file handle function, they work with the file pointer.

fread()

The syntax for the fread() function is

size_t fread(void *ptr, size_t size,
 size_t n, FILE *stream);

- ptr is a pointer to an array in which the data is stored.
- size: size of each array element.
- n: number of elements to read.
- stream: file pointer that is associated with the opened file for reading.
- The fread() function returns the number of elements actually read.

18

fwrite()

- The syntax for the fwrite() function is
- size_t fwrite(const void *ptr, size_t
 size, size_t n, FILE *stream);
- ptr is a pointer to an array that contains the data to be written to an opened file
- n: number of elements to write.
- stream: file pointer that is associated with the opened file for writing.
- The fwrite() function returns the number of elements actually written.

function feof

- int feof(FILE *stream);
- return 0 if the end of the file has not been reached; otherwise, it returns a nonzero integer.

20

Examples

Read 80 bytes from a file.

```
enum {MAX_LEN = 80};
int num;
FILE *fptr2;
char filename2[]= "haiku.txt";
char buff[MAX_LEN + 1];
if ((fptr2 = fopen(filename2, "r")) == NULL) {
   printf("Cannot open %s.\n", filename2);
   reval = FAIL; exit(1);
}
. . . .
num = fread(buff, sizeof(char), MAX_LEN, fin);
buff[num * sizeof(char)] = `\0';
printf("%s", buff);
```

Exercise 2.3

- Write a program that use bloc-based file operations to copy the content of lab1.txt to lab1a.txt
- Use: fread, fwrite, feof

22

Exercise 2.4

A)Improve the program in previous exercise so that it accepts the two filenames as command arguments.

For example: if your program is named "filecpy". You can use it as the following syntax (in Linux): ./filecpy haiku.txt haiku2.txt

B. Write a program having the same functionality as cat command in Linux ./cat1 haiku.txt

Hint

Just use the argc[] and argv[]

```
if(argc<3) { printf("%s <file1> <file2>n",argv[0]); exit(1); }
```

 argv[1] and argv[2] will be the name of source file and destination file.

```
if((fp=fopen(argv[1],"r"))==NULL) {
...
};
if((fp2=fopen(argv[2],"w"))==NULL) {
...
};
```

24

Exercise 2.5: Input and Output of structure

- We assume that you make a mobile phone's address book.
- Define a data structure that can store "name," "telephone number," "e-mail address," and make an array of the structures that can hold at most 100 of the data.
- Input about 10 data to this array.
- Write a program to write the array content using fwrite() into the file for the number of data stored, and read the data into the array again using the fread () function.

File Random Accessing

- Two functions: fseek() and ftell()
- fseek(): function to move the file position indicator to the spot you want to access in a file.
- Syntax

```
fseek(FILE *stream, long offset, int position);
```

- Stream is the file pointer associated with an opened file
- Offset indicates the number of bytes from a fixed position
- Position: SEEK_SET, SEEK_CUR, and SEEK_END
 - SEEK_SET: from the beginning of the file
 - SEEK_CUR: from the current position
 - SEEK_END: from the end of file

26

File Random Accessing

- ftell: obtain the value of the current file position indicator
- Syntax: long ftell(FILE *stream);
- rewind(): reset the file position indicator and put it at the beginning of a file
- Syntax: void rewind(FILE *stream);

Dynamic memory allocation

- Write a program to load a specific portion of the address book data from the file (for example, "3rd data to 6th data" or "2nd data to 3rd data"), modify something on the data, and finally save the data to the file again.
- But, you must allocate necessary minimum memory (the necessary size for "3rd data to 6th data" is four, while two for "1st data to 2nd data") to save the data by the malloc() function.

28

Exercise 2.6

Given a text file call class1EF.txt.
 Write a program to insert a space line between each line in file's content.

Formatted Input Output

- Two function fprintf and fscanf
- Work as printf and scanf.

```
int fscanf(FILE *stream, const char *format, ...);
int fprintf(FILE *stream, const char *format, ...);

fprintf(fp, "%d %s", 5, "bear");
fscanf(fp, "%d %s", &n, s);
```

30

Exercise 2.7

- Write a program to read some numbers from the standard input and output them to an "out.txt" file in reverse order.
 In addition, output a sum of the numbers to the end of out.txt.
- The format loaded from the standard input is that the 1st number is the number of data, and the 2nd and proceeding numbers are for process. In a case when you input
- 4 12 -45 56 3
- "4" is the number of numbers that follows, and the remainder "12 -45 56 3" should be an output numbers onto the "out.txt" file. The output to "out.txt" is,
- 3 56 -45 12 26
- The last number "26" is the sum of four numbers.
- Because the number of numbers you input changes each time, you must dynamically allocate memory for the number of data: using the malloc() function.
